# **IMPROVING THE SENSITIVITY OF THE CDMS DETECTOR TO DARK MATTER PARTICLES: UNDERSTANDING SOURCES OF NOISE IN THE EXPERIMENT**

Jorge D Morales

Astronomy and High Energy Physics Seminar  
Universidad Iberoamericana  
08 / 22 / 2014

# OUTLINE

- I. Motivation: Understanding Dark Matter in the Universe
- II. The CDMS Experiment and the Hunt for Dark Matter Particles
- III. Separating Real Particles From Noise
- IV. Identifying Potential Sources of Noise: Methods and Results
- V. Looking Towards the Future
- VI. Conclusions

# EVIDENCE OF DARK MATTER FROM MULTIPLE SOURCES

## Example 1

- The rotational velocity of stars in the outer part of a galaxy 'should' match the amount of mass observed from stars and gas in the inner part of the galaxy
- Observed velocity is what you would expect if there is a large amount of mass you can't see

## Example 2

- Einstein ring: Large amounts of dark matter in a "near" galaxy can lens the light from a galaxy behind it.

# EVIDENCE OF DARK MATTER FROM MULTIPLE SOURCES Continued...

## Example 3

- Cosmic Background Radiation measurements indicate that there is a large amount of mass in the universe not in atoms
- Freeze-out cross section dictates that other interactions should be *weak* (via a force similar in strength to the weak force)

## Example 4

- Colliding clusters of galaxies provide evidence that Dark Matter is likely to be a particle
- Interacts gravitationally

# IF DM IS A PARTICLE, WHAT DO WE KNOW ABOUT IT? HOW CAN WE DISCOVER IT?

- Weakly Interacting
  - Massive Particle
  - Neutral
  - Neutrinos are ruled out
  - Most believe it must be a new particle, i.e. from Supersymmetry
- WIMP

## Possible ways to discover DM:

CDMS is an experiment designed to detect DM interactions with SM particles in a detector (diagram with time going vertically upward)

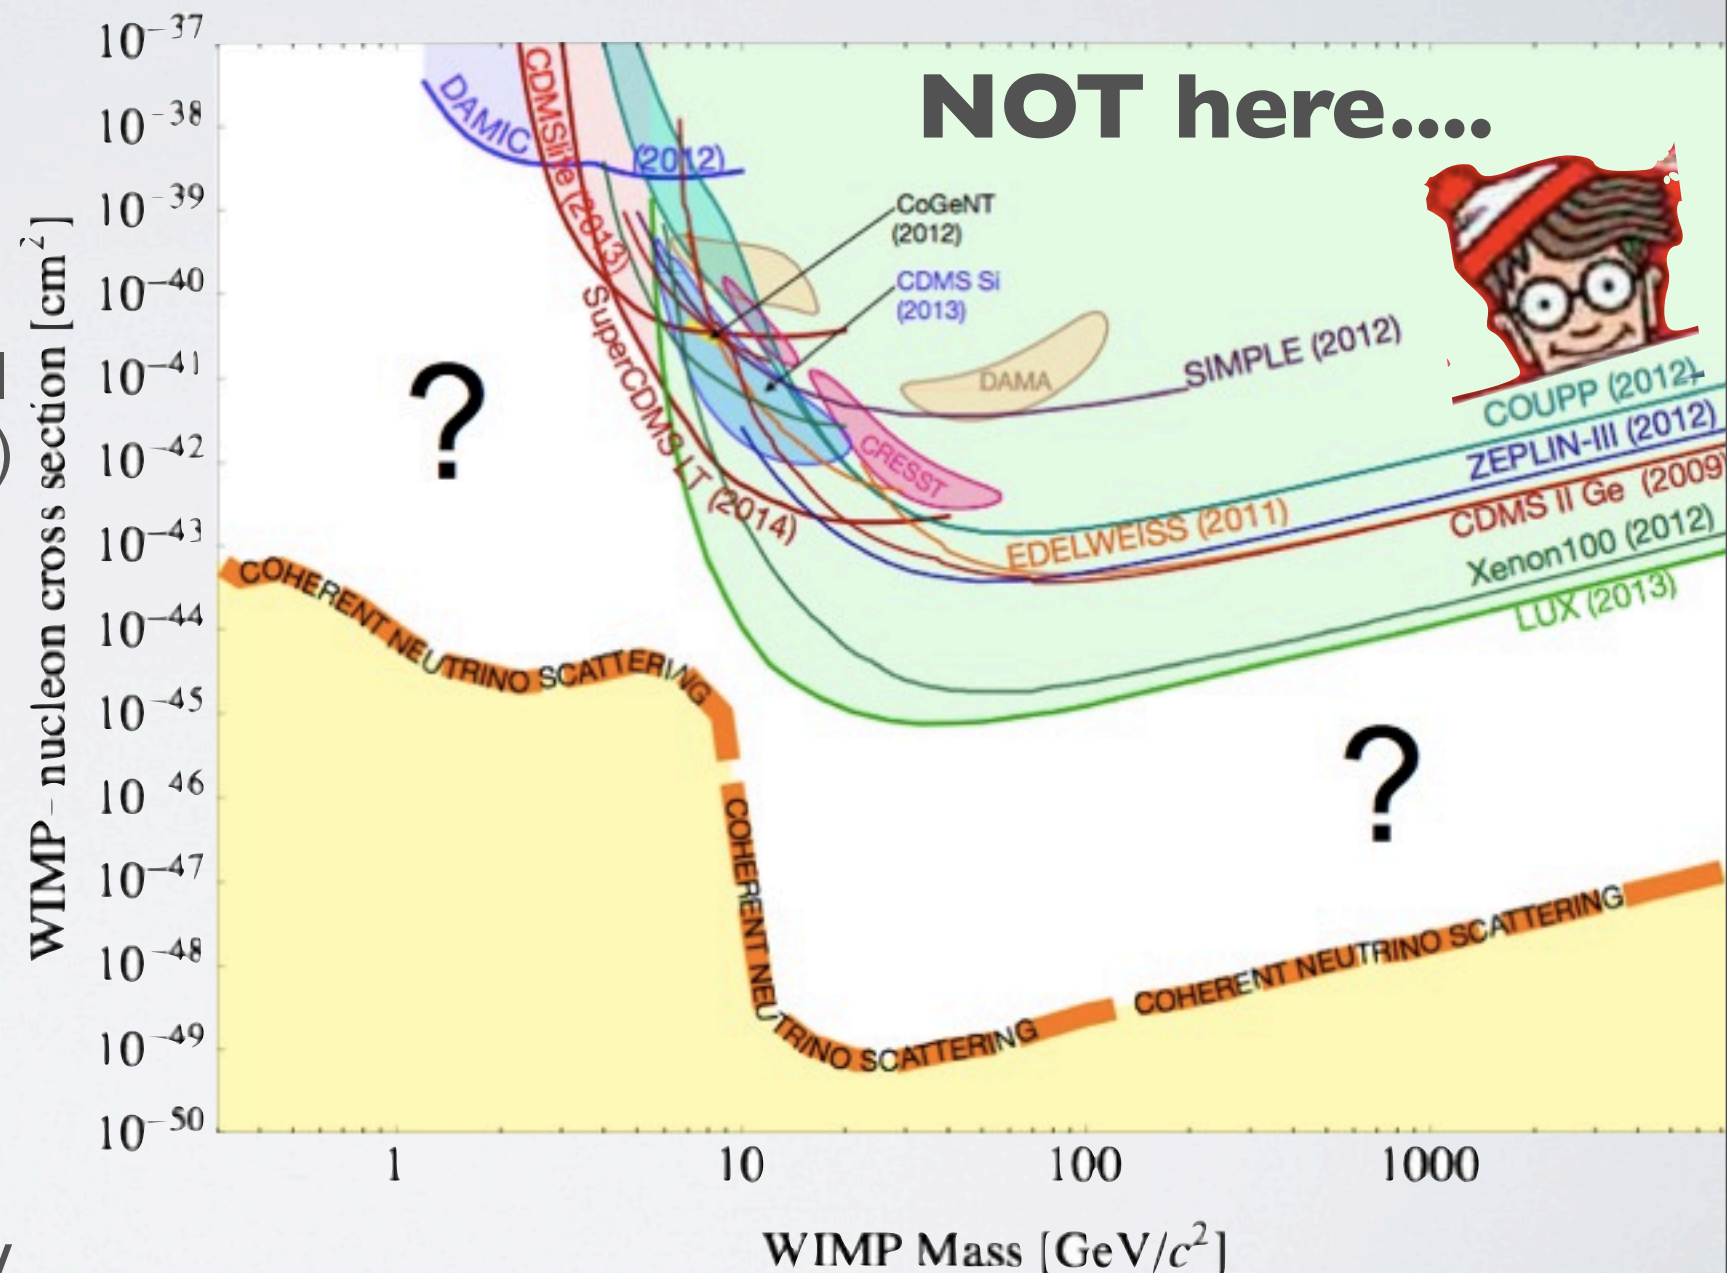

## DARK MATTER DIRECT DETECTION EXPERIMENTS

- CDMS (600g Ge Crystal detectors) → SuperCDMS Soudan and SNOLAB
- DAMA (100 kg sodium iodide crystal) → DAMA/LIBRA (250 kg, Gran Sasso, Italy)
- XENON10 (15kg liquid xenon) → XENON100
- COGENT (440g Ge detectors)
- EDELWEISS (800g Ge Crystal detectors) → EDELWEISS III
- COUPP (30L Bubble chamber)
- ZEPPLIN III (12kg Gas and Liquid Xenon)
- LUX (370kg Liquid Xenon)
- Lux and Zepplin combined to create LZ which is the only other DOE experiment (other than CDMS) to move forward for G2

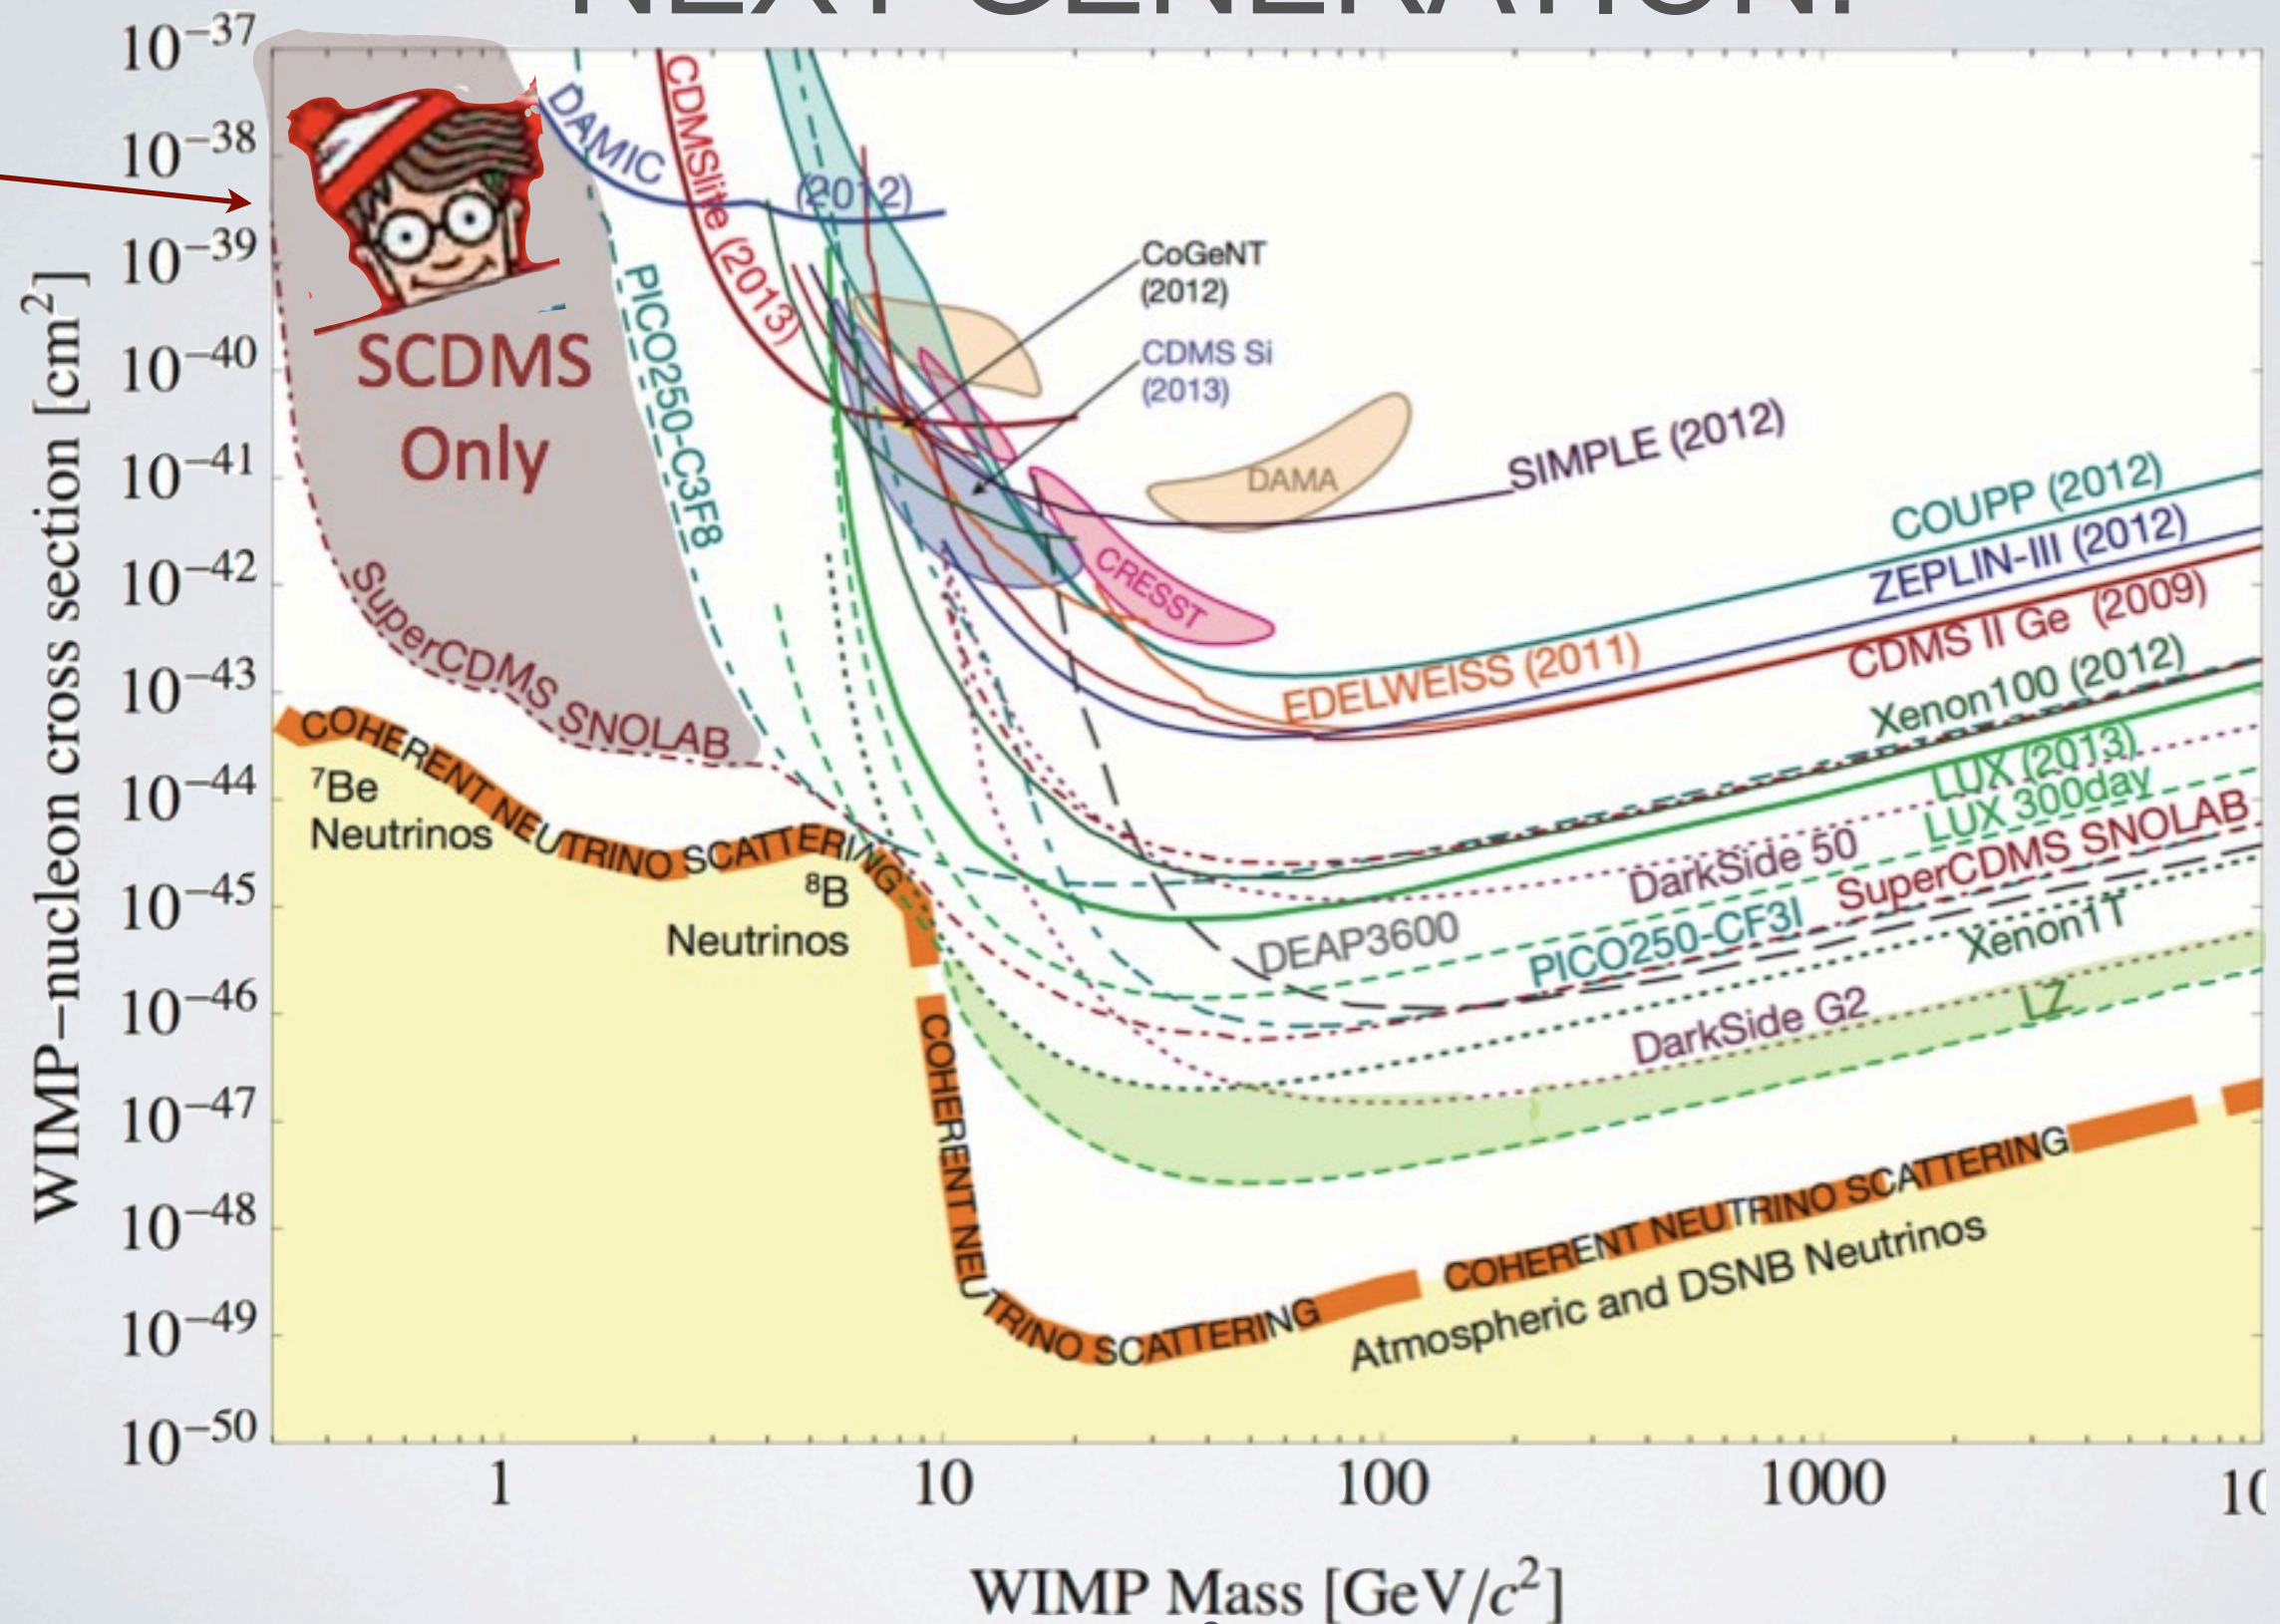

# WHAT DO WE KNOW SO FAR?

- We know how to exclude regions where we are *certain* that WIMPs don't exist  
(DAMA region is a controversial place that could be a discovery)
- Experiments like CDMS probe to their sensitivity limits to *find* or *exclude* a WIMP signal
- Different masses interact differently with the detectors so the sensitivity depends on the assumed mass

## NEXT GENERATION!

## II. CDMS and the Hunt for Dark Matter

### DARK MATTER PARTICLES AND THE CDMS DETECTOR

Phonons

- Earth is moving through the DM Halo of the Milky Way
- Look for an interaction between a DM particle and a heavy nucleus in a sensitive detector (CDMS)

Nuclear Recoil produces vibrations (phonons) that propagate in the lattice

Few keV of energy deposited in the crystal lattice (depends on DM mass)  
How often this happens depends on the DM-nucleon cross section

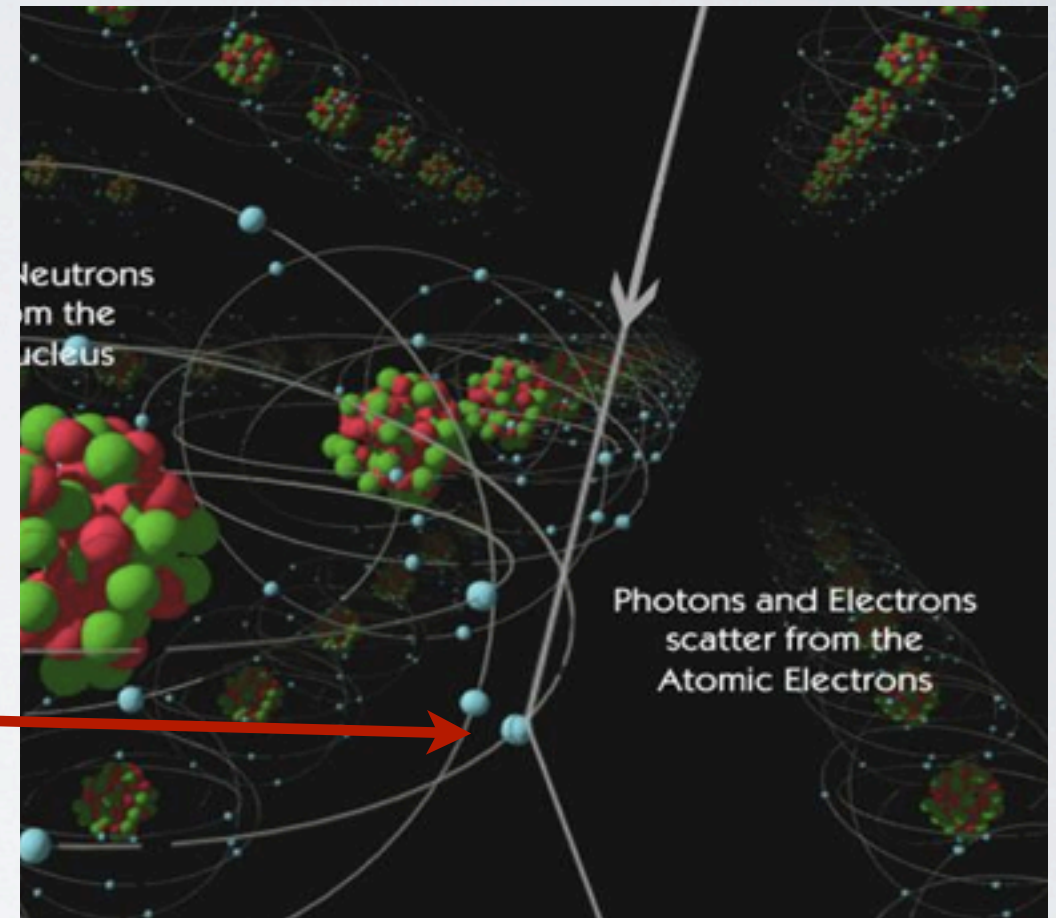

## II. CDMS and the Hunt for Dark Matter

# DARK MATTER PARTICLES AND THE CDMS DETECTOR

Ionization

- Other EM interacting particles scatter electrons from the atomic orbitals
- A DM particle would not scatter electrons

Scattered electrons propagate as electron/holes in the crystal, and we collect it as a current in the detector,

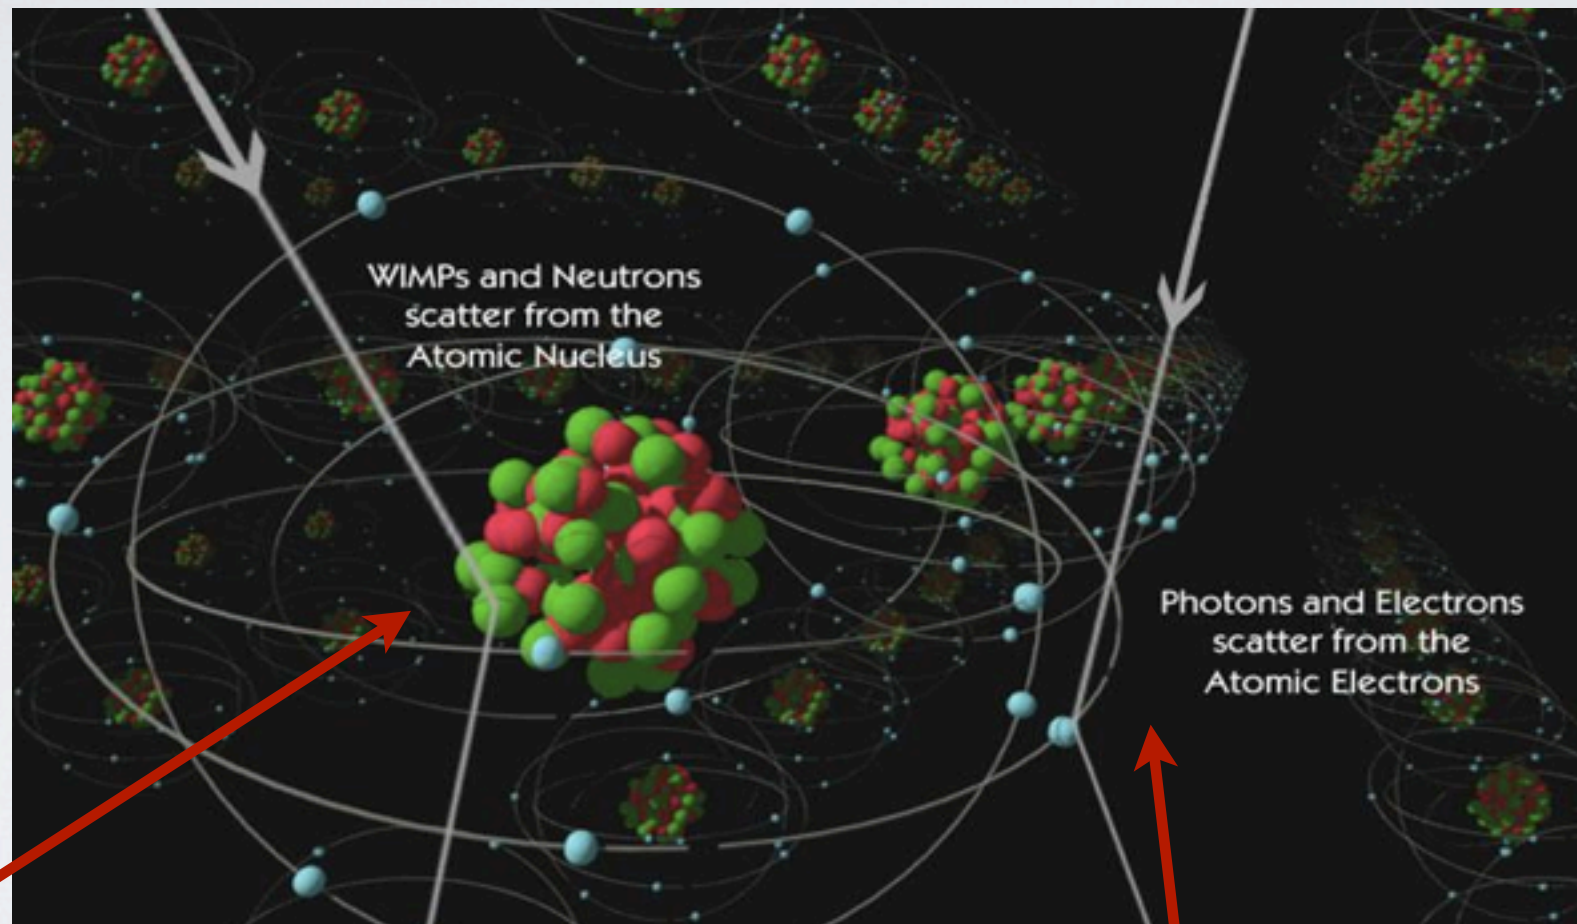

Not as sensitive as phonons but it is easier to collect ionized charge. Particles need to be traveling fast, otherwise ionization is not produced.

## II. CDMS and the Hunt for Dark Matter

### DARK MATTER PARTICLES AND THE CDMS DETECTOR

Phonons:

- Dense energy deposition
- The nucleus is heavy
- Relativistically slow

Ionization:

- Sparse energy deposition
- Electrons are kicked at fast velocities
- Near relativistic ( $v/c \sim 0.3$ )

# II. CDMS and the Hunt for Dark Matter

## CRYOGENIC DARK MATTER SEARCH (CDMS) EXPERIMENT

Detector is deep underground to keep Cosmic Background from faking DM interaction

Sensitive to 2keV of energy deposit

Detectors at 80mK  
Right at transition between being  
normal conducting and  
superconducting

Ancient lead is the most 'dead' -  
inactive - material  
Was picked up from a sunk French  
boat

- Shielding:
- Polyethylene
  - Ancient Lead
  - Low Activity Lead

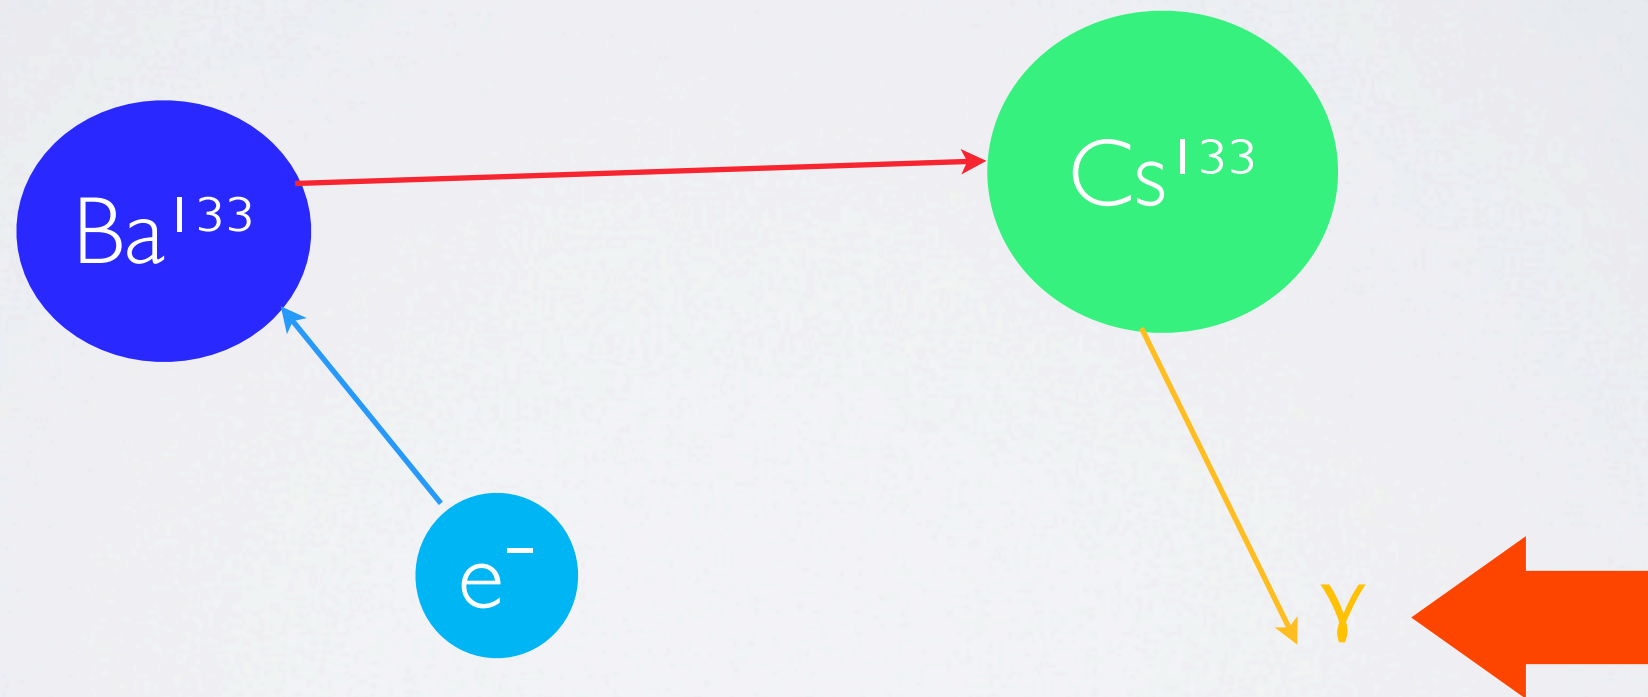

## II. CDMS and the Hunt for Dark Matter

### CALIBRATION SOURCES FOR BACKGROUND SIMULATION

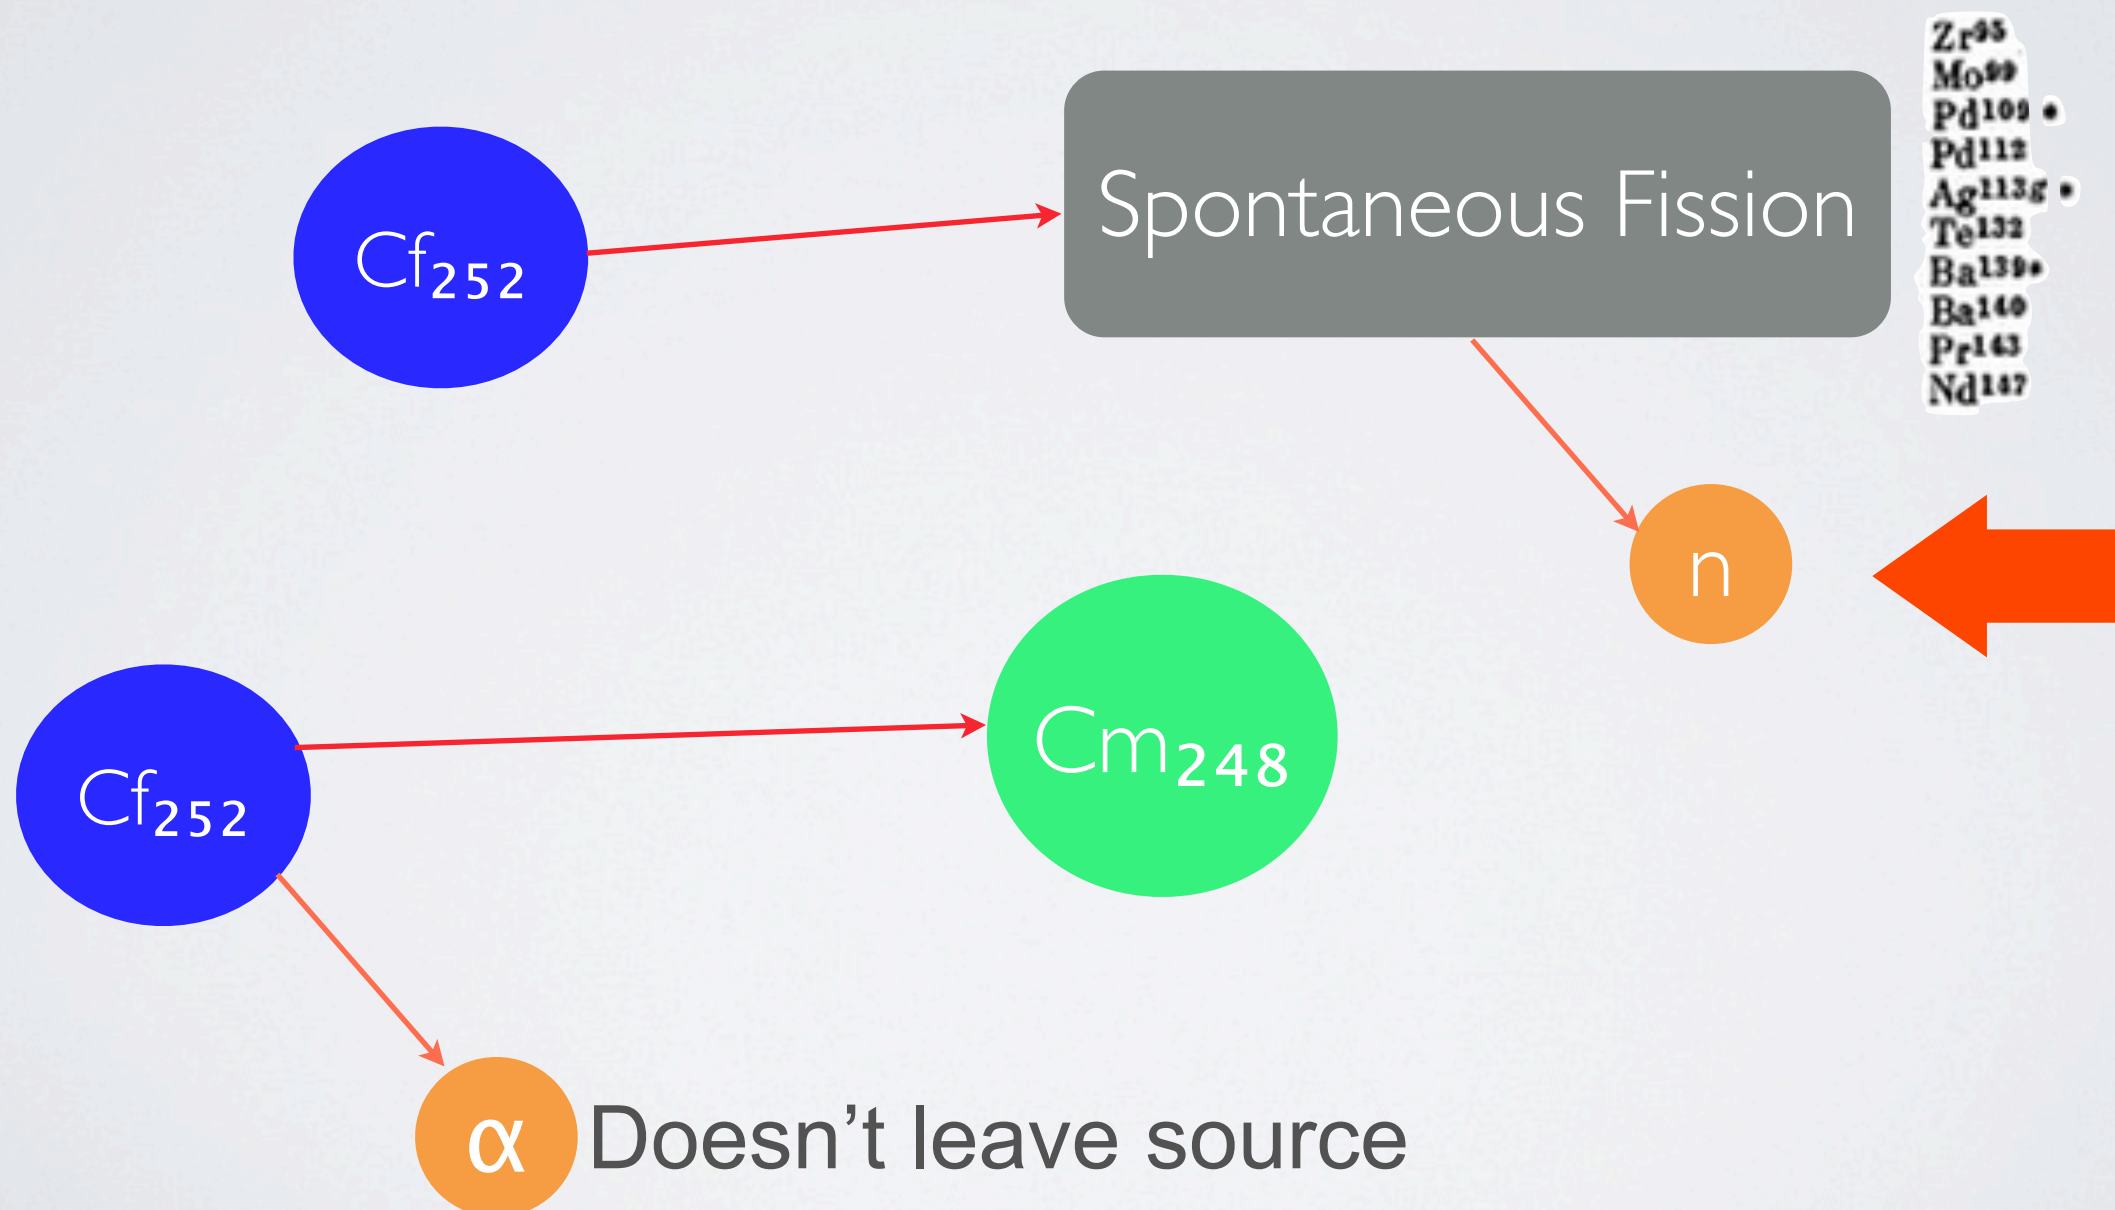

- $\text{Ba}^{133}$  as a source of gammas
  - producing electron recoil, charge calibration

## II. CDMS and the Hunt for Dark Matter

### CALIBRATION SOURCES FOR BACKGROUND SIMULATION

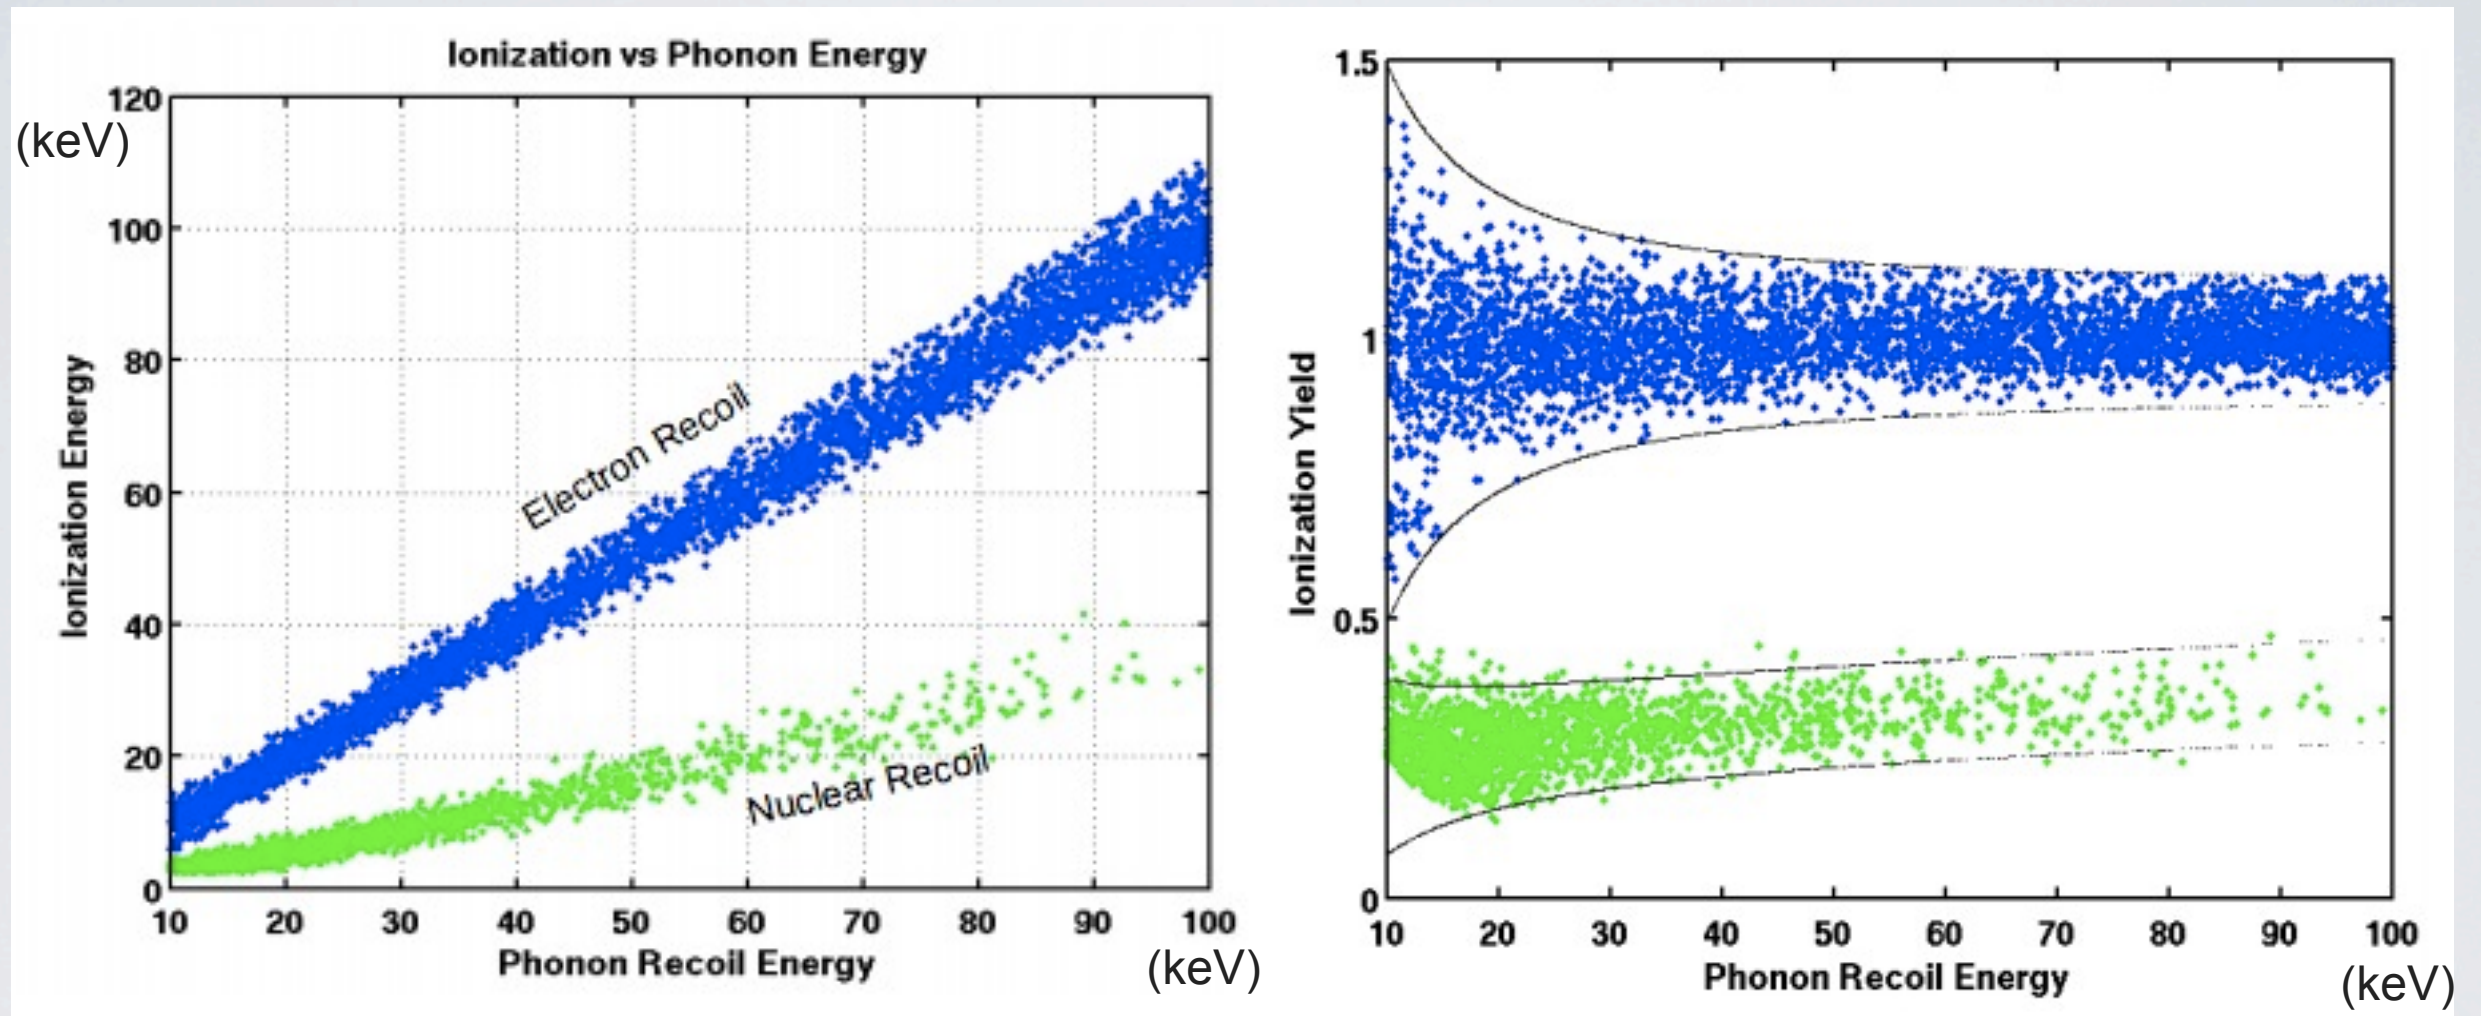

- $\text{Cf}_{252}$  as a source of neutrons  
producing nuclear recoil, phonon calibration

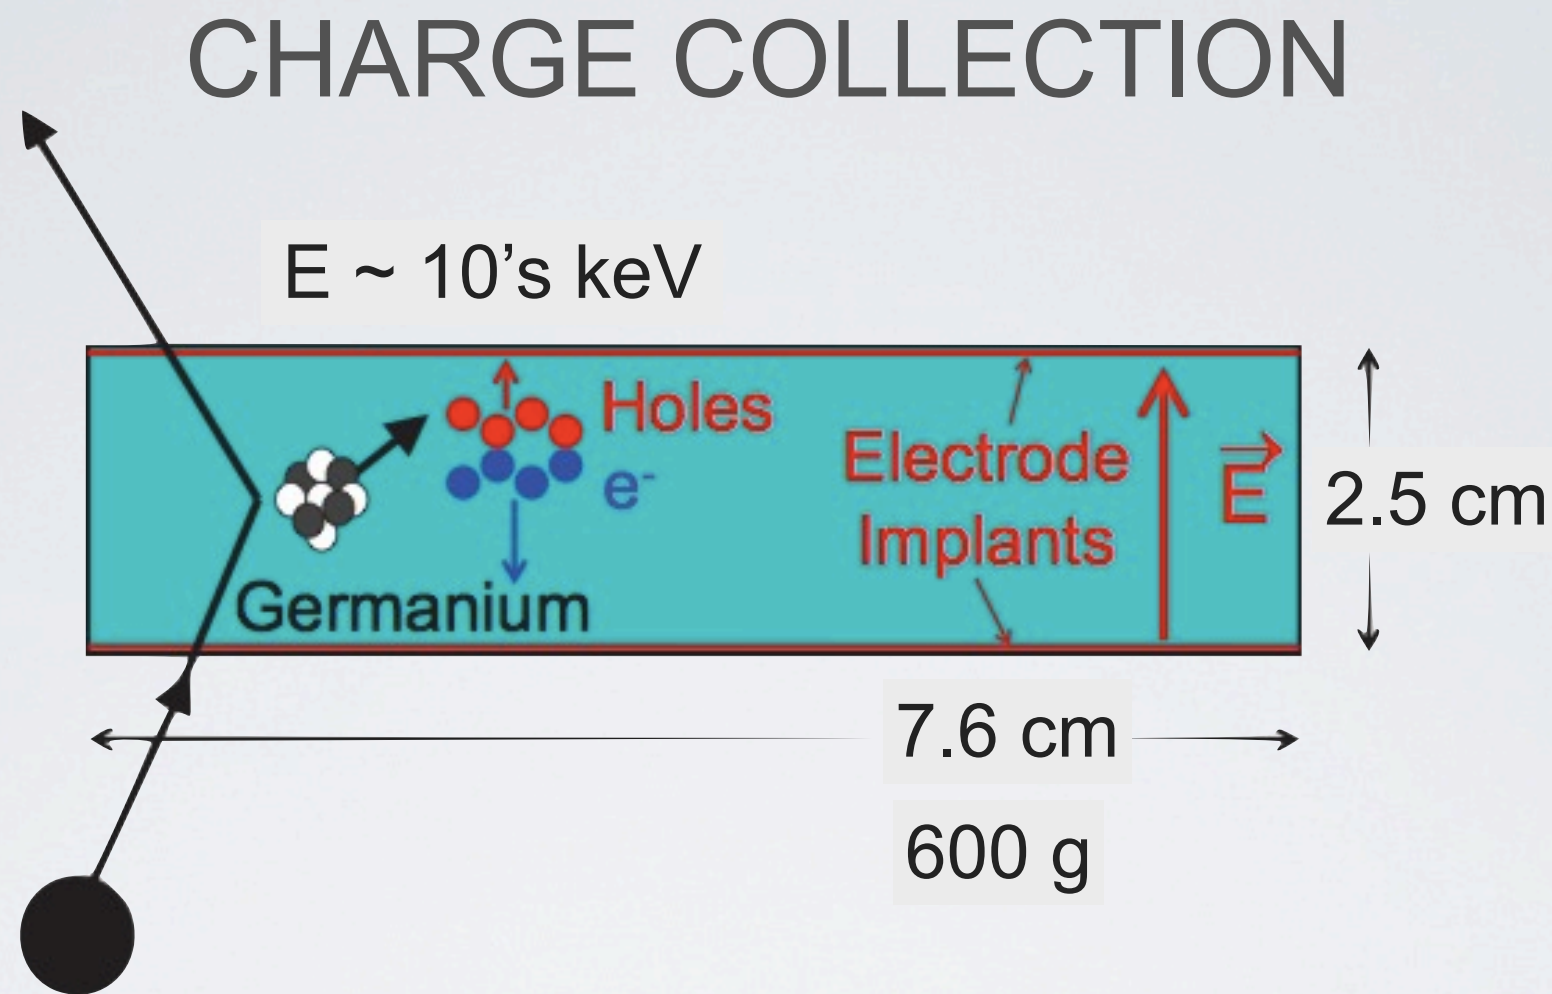

## II. CDMS and the Hunt for Dark Matter

### PARTICLE DISCRIMINATION

- electron recoils from gamma source (Ba Calibrations)
- nuclear recoil from neutron source (Cf Calibrations)
- DM signal looks more like this

## II. CDMS and the Hunt for Dark Matter

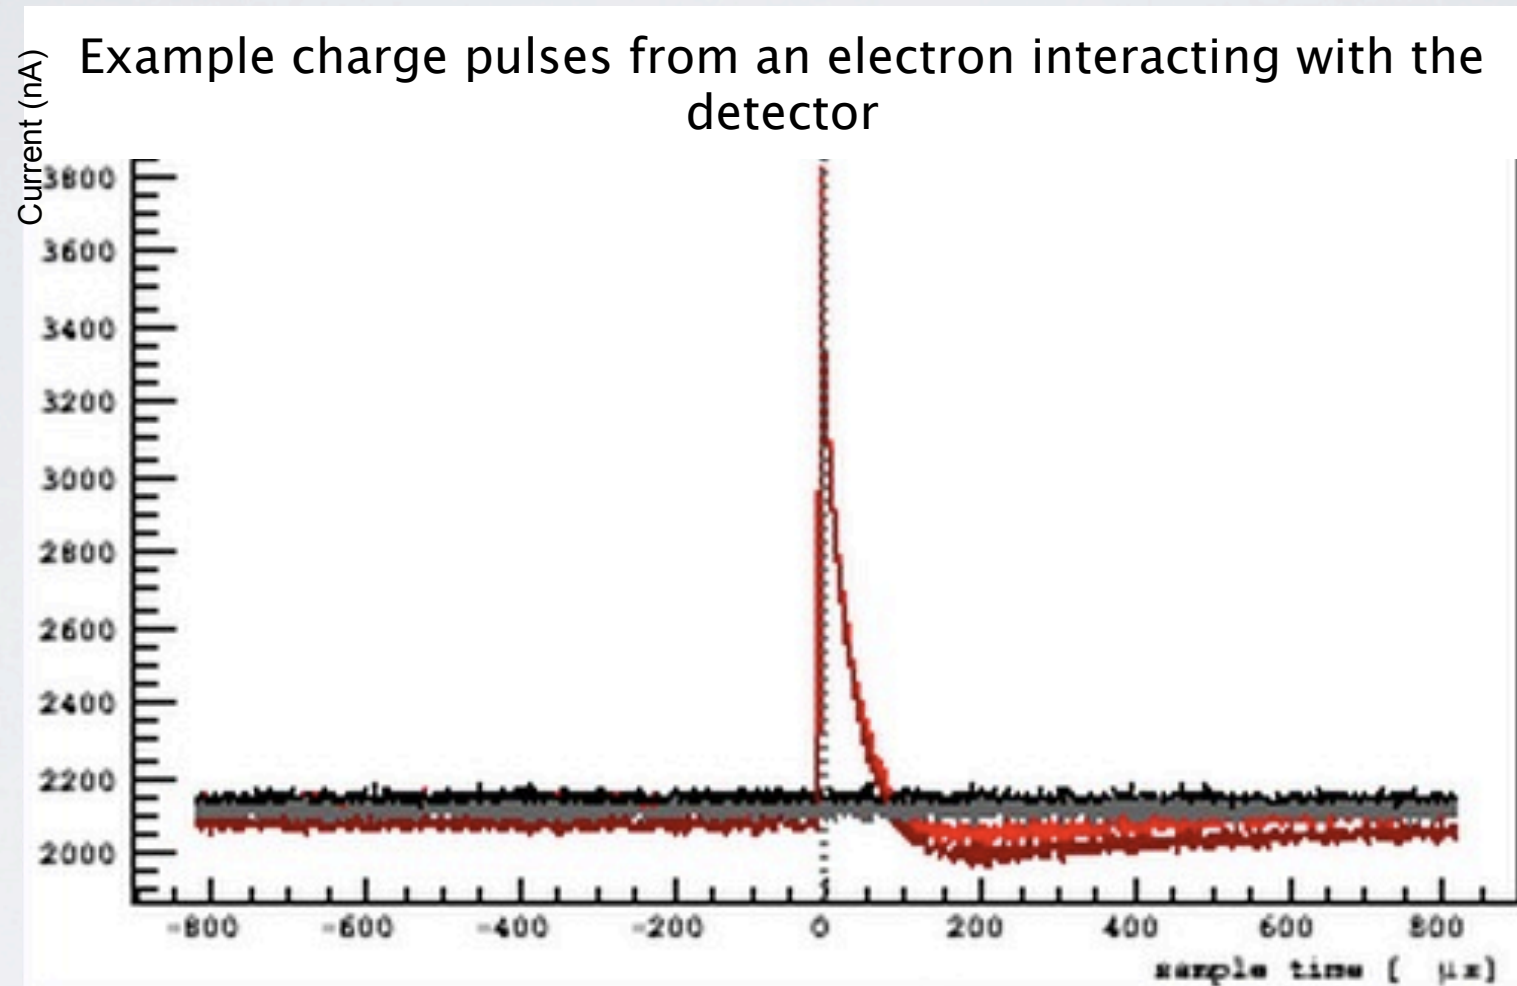

Charge Lines

- As the electron/holes are liberated they are transported by the electric field in the crystal and collected by the charge lines in the **T**ransition **E**dge **S**ensor
- Charge is easy... phonons are hard!

### CHARGE SIGNAL

## II. CDMS and the Hunt for Dark Matter

# FROM PHONONS TO A SIGNAL OUT OF A TRANSITION EDGE SENSOR (TES)

- A DM particle will interact and create vibrations in the lattice: Phonons
- Phonon production and collection process:
  - ① phonons created in the interaction
  - ② phonons travel to the aluminum
  - ③ break up Cooper Pairs and couple to one of the electrons in the pair
  - ④ electrons are absorbed by the Transition Edge Sensor (TES) changing it's temperature (which changes its resistance, and the amount of current that flows through it)

Phonon Trap

Transition Edge Sensor (TES):

Resistance as function of temperature in the transitioning phase (Super/Normal - conducting) → the changing resistance creates a signal

## II. CDMS and the Hunt for Dark Matter

# FROM THE TES TO THE SQUID: GETTING SIGNALS OUT OF THE DETECTOR

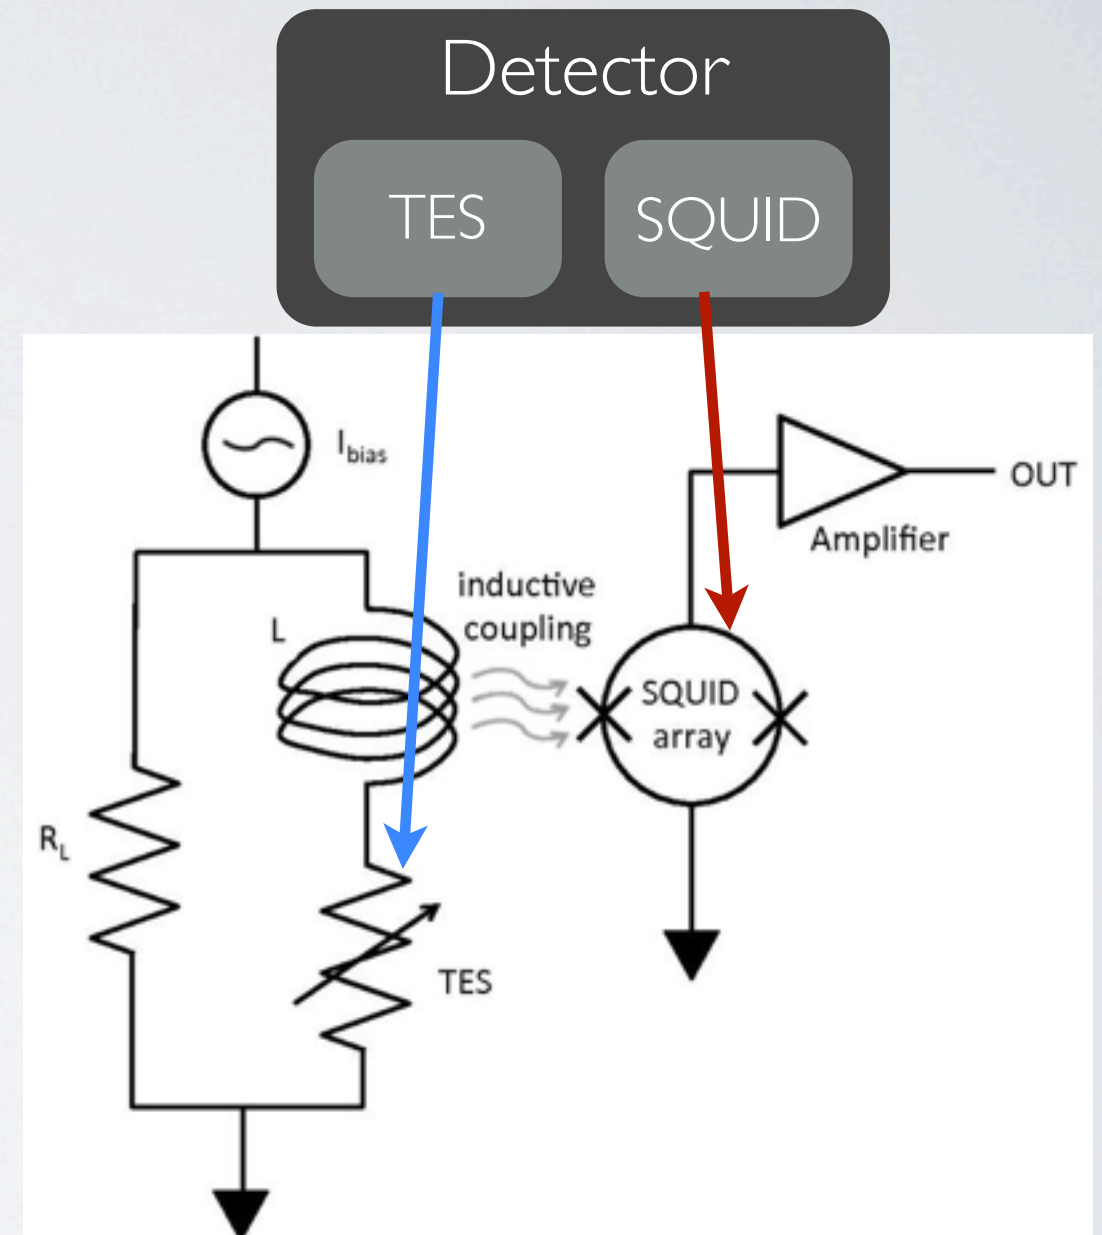

- Superconducting QUantum Interface Device (SQUID): measures the current change of the TES. It's output is what we call the 'phonon pulse'

(inductive coupling)

each TES sector  
coupled to a SQUID

Each SQUID  
provides a PULSE

PULSE is sent to  
Downstream Electronics

# PHONON SIGNAL READ-OUT

# III. Separating Real Particles From Noise

## LOOKING AT DETECTOR PHONON PULSES

- When a particles interacts we get phonon pulses:
  - A signal in all 8 channels

- When no particle hits the detector:
  - Just read out 'noise' from detector (see right)
- Problem: Signal from a DM particle is not as big as above, so we need to be really sensitive and distinguish between a small pulse from the noise (below)

### III. Separating Real Particles From Noise

## WE DID A SPECIAL SET OF STUDIES TO UNDERSTAND THE SOURCES OF NOISE IN THE DETECTORS

- Want to be sensitive to light DM particles which don't deposit much energy in the detector
- Sensitivity is determined by the ability to separate small real-particle-pulses (signal) on top of the detector output when there is no particle (noise)
- The amount of noise also affects our ability to measure the amount of energy deposited if we believe the pulse is from a real particle

### **GOALS:**

- **Understand the sources of noise**
- **Make suggestions on how to reduce them**

# III. Separating Real Particles From Noise

MY PROJECT FOCUSED ON UNDERSTANDING THE SOURCES OF NOISE IN THE PHONON PULSES

Where in this chain does noise come from?

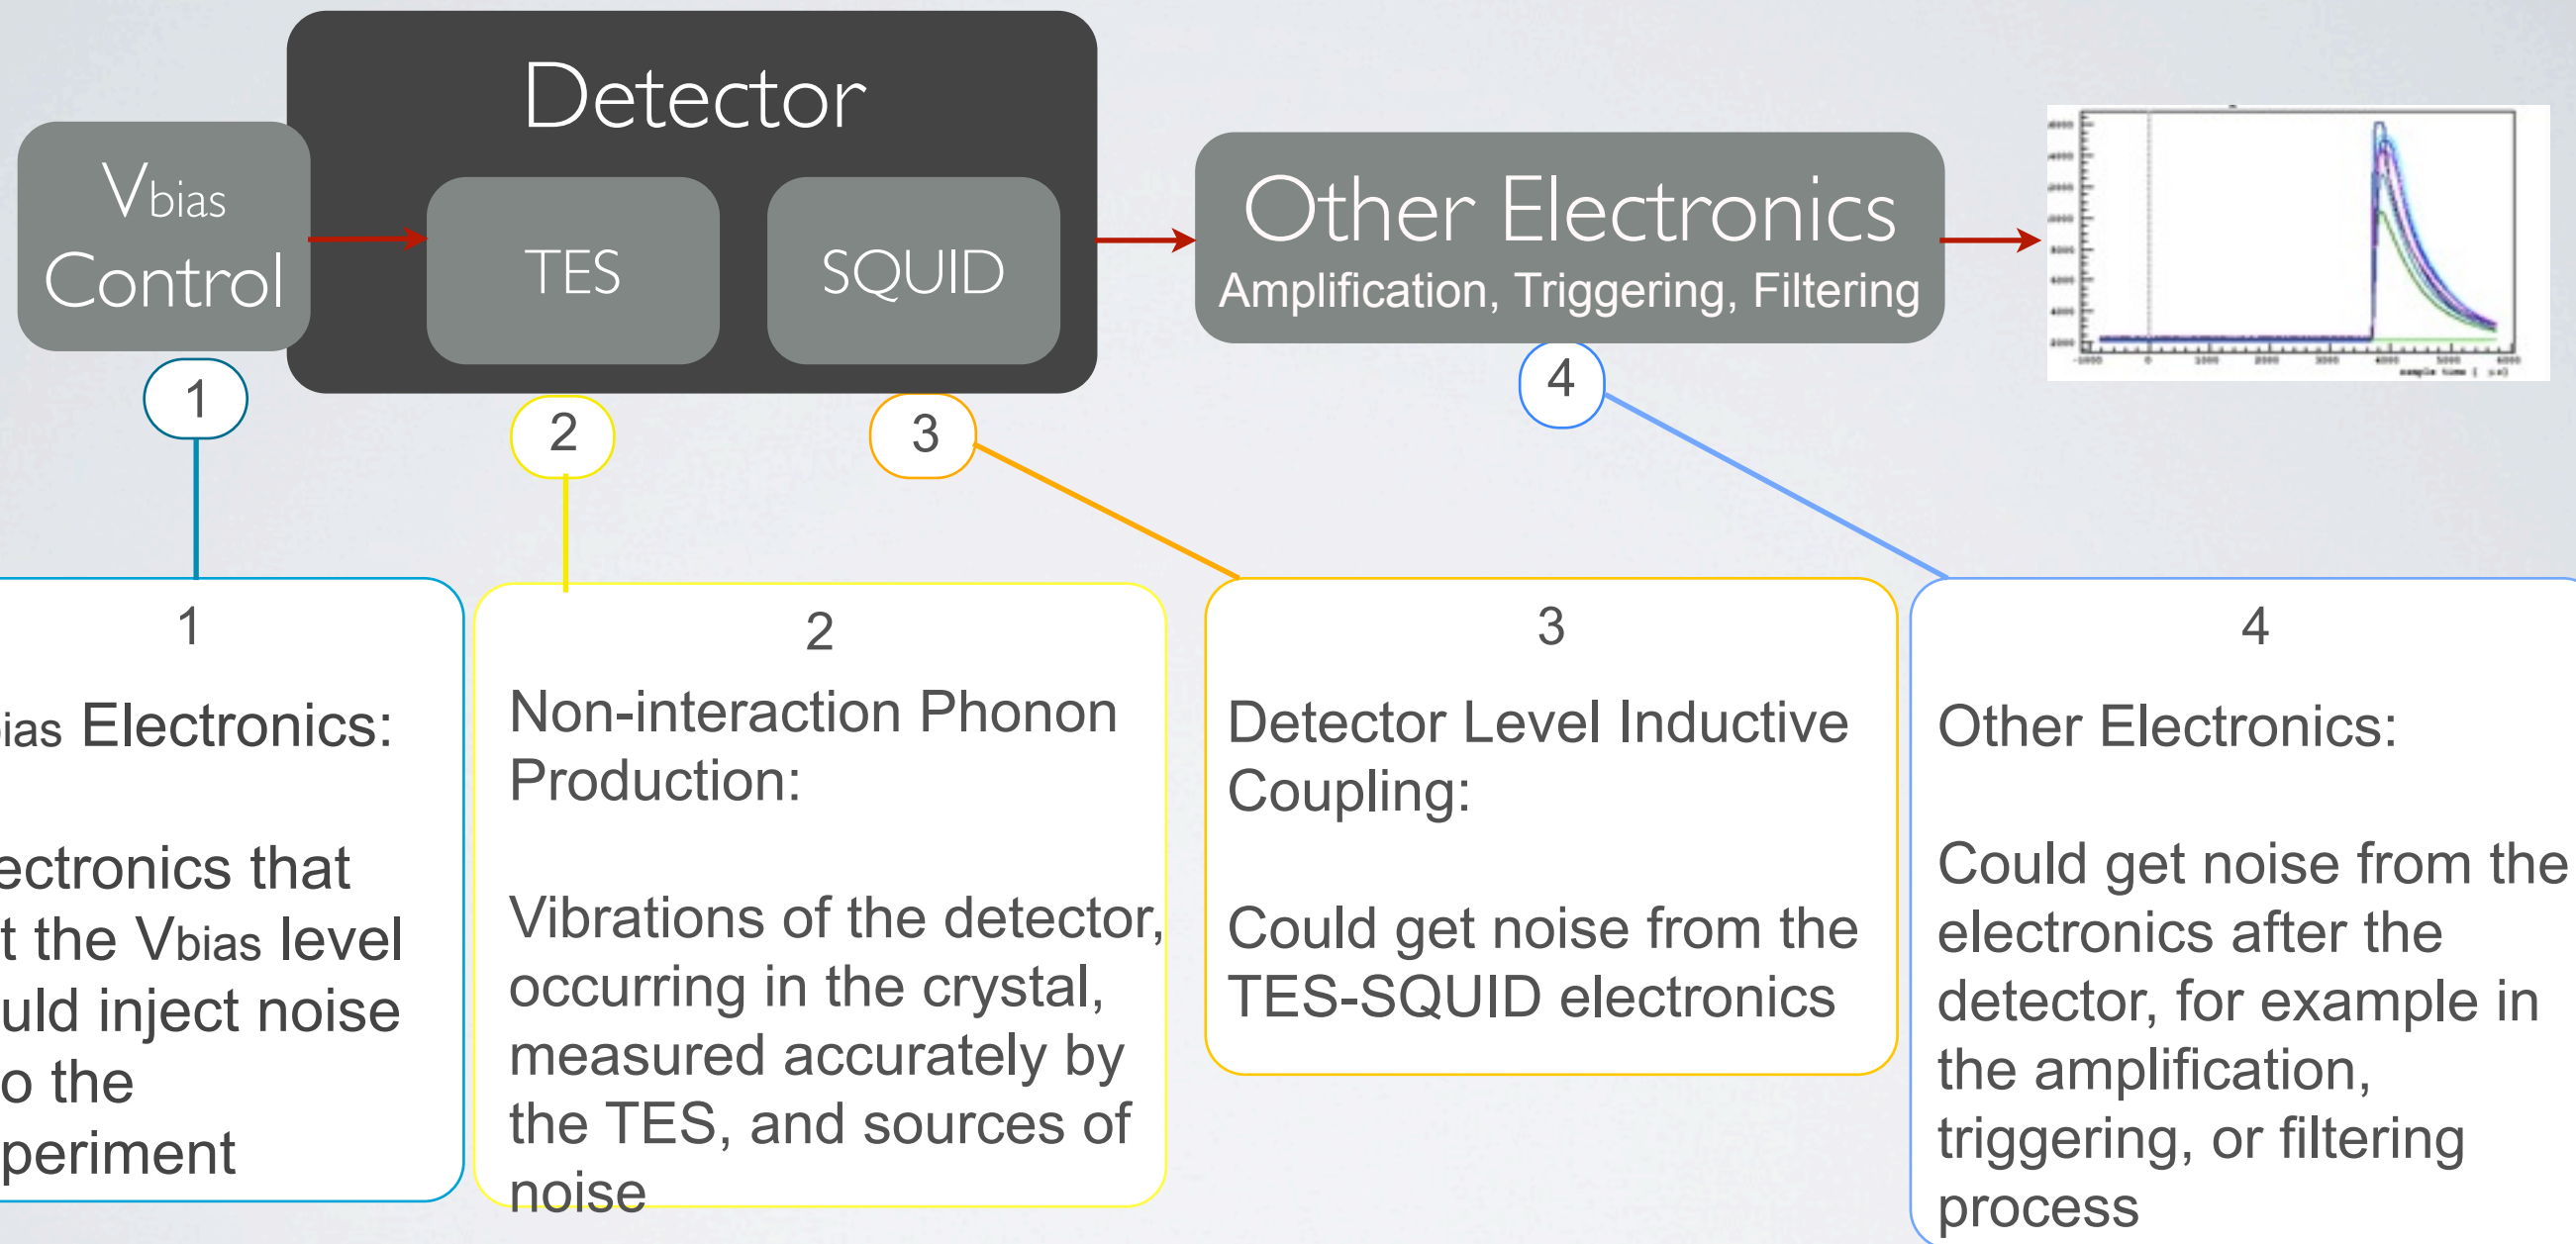

### III. Separating Real Particles From Noise

## HOW DO WE STUDY THE AMOUNT OF NOISE FROM THE DETECTOR?

- Take data when no particle interactions are occurring
- Randomly select a time to start writing out data:
  - unlikely to have real particles interacting
  - pure sample of 'noise'
- The longer the time, the better information we have for noise analysis
  - 750 $\mu$ s is a typical real particle pulse time
  - Total time  $>$  (2x before + 750 $\mu$ s + 5x after)
  - Total time  $\sim$  100,000  $\mu$ s
- Ratio of interaction of a 'cosmic' background is  $\sim$ 1 per minute so our total time is ok

# POSSIBLE SOURCES OF NOISE IN THE EXPERIMENT

## IV. Potential Sources of Noise: Method

# METHODS FOR STUDYING THE AMOUNT OF NOISE

- Sources of noise expected to occur at specific frequencies (we see that in PSDs from collected data... more soon)
- Look at the data in the Frequency Domain
- Use Fast Fourier Transforms (FFT) → Power Spectral Density Function (PSD)

Example: Breaking a Pulse with FFT

- y: amplitude

- x: time

- y: amplitude in the Power Spectrum

- x: frequency

- Look at many events (lots of noise) to see at which frequency there is most noise

## IV. Potential Sources of Noise: Method

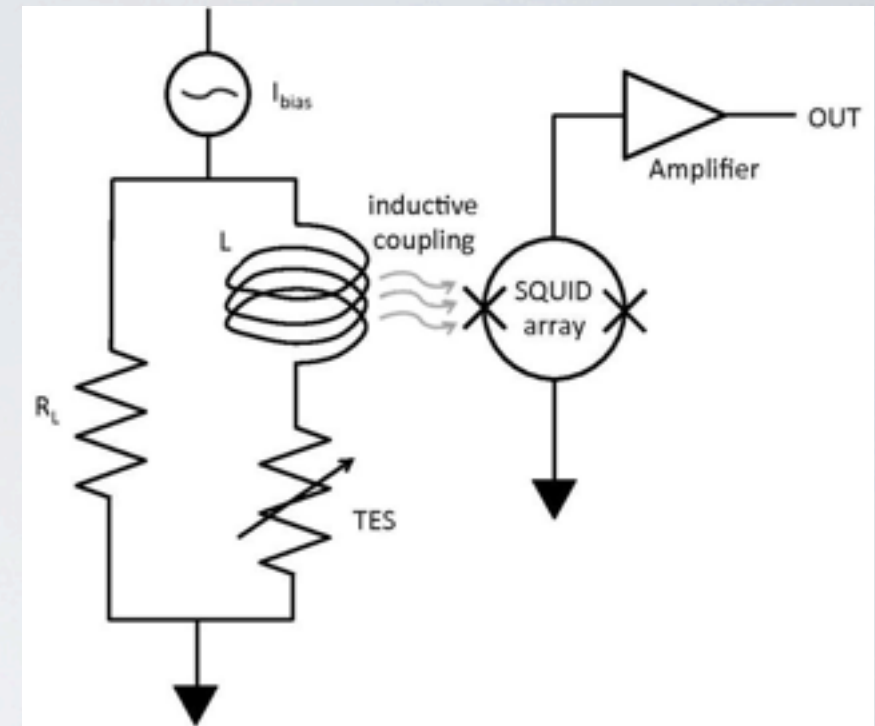

# BASE NOISE OF THE TES/SQUID CIRCUIT

### Baseline

- 'Johnson Noise'
  - Intrinsic to the TES/SQUID circuit
  - Characteristic of the amplification of the TES/SQUID pulse
- Depends on the Resistance and Temperature of the elements in the circuit
  - proportional to the Resistance and Temperature product of each element

### Cut-off frequency

- The cut-off frequency is determined by the impedance

# STANDARD CONFIGURATION DATA

- Baseline Noise: from TES/ SQUID electronics (Johnson Noise)
- Rising region: will show this is from low frequency detector vibrations  $< 60$  Hz
- Spikes: noise from various sources 100 Hz - 1kHz (phonon, detector electronics, or other electronics noise)

## IV. Potential Sources of Noise: Method

# COLLECTING SAMPLES OF NOISE IN DIFFERENT DATA TAKING CONFIGURATIONS

A. Standard Configuration:  
Usual configuration for data  
 $V_{\text{bias}} = V_{\text{threshold}}$

- TES is in transitioning phase between normal conducting and superconducting
- Phonons are collected and detector is sensitive to them (gives pulses)

*Standard / Transitioning*  
Sensitive to phonons

B. Normal Conducting:  
Bias current set at 1000  $\mu\text{A}$   
 $V_{\text{bias}} \gg V_{\text{threshold}}$

- Resistance never changes much, (amplified) current of SQUID is always small
- Phonons from the detector don't create output signals
- There is minimum amplification of any noise from TES/SQUID

*Normal Conducting*  
Insensitive to phonons  
27

C. Super Conducting:  
Bias current set at 0  $\mu\text{A}$   
 $V_{\text{bias}} \ll V_{\text{threshold}}$

- Resistance never changes much, (amplified) current of SQUID is always large
- Phonons are not amplified so no output signal from phonons
- Maximum amplification from any TES/SQUID noise

*Superconducting*  
Insensitive to phonons

# IV. Potential Sources of Noise: Method

## COMPARING ALL THREE SETS OF DATA AT THE SAME TIME (FOR A SINGLE DETECTOR) AND DRAWING QUALITATIVE CONCLUSIONS

- Other Electronics:
  - Peaks of this kind have a noise ratio of 1-to-1 regardless of mode
  - 60 Hz noise always present
  - The amount of noise at this frequency is always the same
- Noise from Phonons:
  - Only see this rising noise in Standard Mode (not in Superconducting nor Normal Conducting)
  - Indicates it is due to phonons that are always present in the detector
  - Also see some phonon spikes (not present in modes insensitive to phonons)
- Spikes due to  $V_{\text{bias}}$  Electronics / Inductive Coupling:
  - Change in the amplitude of peaks
  - Amplitude depends on resistance ratio of the different modes

## IV. Potential Sources of Noise: Results

MOVING FROM OUR EXAMPLE DETECTOR TO NOISE IN OTHER DETECTORS. NOT ALL DETECTORS ARE THE SAME

- Again see the 60 Hz peak (true for most detectors)
- Some detectors have spikes due to "phonon peaks", not just the slope (build-up). Due to cryogenics?
- Many peaks/features are combined electronics noise (from  $V_{\text{bias}}$ /Inductive and Other Electronics)

## IV. Potential Sources of Noise: Results

# RESULTS FOR THE FULL SET OF DETECTORS

- For each detector we have qualitatively identified the principal sources of noise in two regions
- Comment on noise in two different regions:
  - < 60 Hz Background
  - 100 Hz - 1 kHz peaks

## IV. Potential Sources of Noise: Results

# RESULTS FOR (ALMOST) ALL DETECTORS

- < 60 Hz Background Results:
  - Most of the detectors (13/15) clearly show real phonon noise

## IV. Potential Sources of Noise: Results

# RESULTS TRUE TO SOME DETECTORS

- 100 Hz - 1 kHz peaks
  - Different detectors show different noise sources, but overall noise is similar in all channels of the same detector (as opposed to some channels)
  - Other Electronics noise doesn't appear in all channels of same detector
  - All detectors show real phonon source peaks
  - Some show additional  $V_{\text{bias}}$ /Inductive peaks, others show no sources of this kind
  - 6/15 are Phonon dominated
  - 6/15 show Other Electronics peaks
  - 9/15 are  $V_{\text{bias}}$ /Inductive and Phonon dominated

# V. Looking Towards the Future

## IDEAS TO REDUCE/CANCEL NOISE IN THE FUTURE

- Flip the Polarity of half of the channels:
  - Invert  $V_{\text{bias}}$  of 4 out of 8 channels
  - Real phonon signal should flip
  - Electronics noise will not
- Potentially cancel all 'Electronics' noise
- Complications:
  - Noise should be properly identified and **STRONGLY** correlated between channels, if not, then it means that noise is not matching exactly the same frequency, so we are killing more than just noise

Electric

Phonon

## V. Looking Towards the Future

# LOOKING TOWARDS THE FUTURE AS THE CDMS EXPERIMENT MOVES TO SNOLAB

- A major upgrade to the experiment where the CDMS detectors will be located, at SNOLAB (Ontario, Canada), was just approved!
- All detectors have some amount of noise that appears to be due to vibrations, so better casing and supporting structure could really help (independent studies relate the Cryocooler noise with the pulses)
- Better electronics could also help suppress all electronics noise, mostly at TES/squid level, but also downstream
- Inverting the Bias on half of the output channels may lead to electronics (post TES) noise suppression - currently exploring this idea, we are not certain if it is possible to do without suppressing too much signal

## V. Looking Towards the Future

# SNOLAB

# CONCLUSIONS

- CDMS is currently the most sensitive low-mass dark matter detector in the world and is expected to be so long into the future
- Noise in the detector directly impacts our sensitivity to low mass Dark Matter particles
- We have uncovered and understood (qualitatively) a number of sources of noise in the experiment and made recommendations to help remediate some of them
- Looking forward to the next generation of the CDMS Experiment with improved detectors, casing, and readout equipment at SNOLAB which was just approved

# ACKNOWLEDGEMENTS

## DIRECT DETECTION

**Sensitive to 2keV of energy deposit  
(LUX: ~3.3 keV)**

- CDMS (Cryogenic DM Search) → Super CDMS
- DAMA (100 kg sodium iodide crystal) → DAMA/LIBRA (250 kg, Gran Sasso, Italy)
- XENON10 (15kg liquid xenon) → XENON100
  - Ionization (eV,  $\epsilon \sim 20\%$ )
- KIMS (Korea Invisible Mass Search)
  - Scintillation (keV,  $\epsilon \sim 1\%$ )
- XMASS (800 kg spherical liquid Xe, Japan)
  - Phonon (meV,  $\epsilon \sim 100\%$ )

## II. CDMS and the Hunt for Dark Matter

# FROM A PARTICLE INTERACTION TO A SIGNAL OUT OF A TRANSITION EDGE SENSOR

- A DM particle will interact via vibrations of lattice: Phonons

- Phonon production and collection process:

- 1 super-rapid phonons (*athermal*)
- 2 phonons break superconducting cooper pairs
- 3 cascade phonons are produced
- 4 phonons couple to freed electrons
- 5 finally they diffuse into the tungsten Transistor Edge Sensor (TES)

*athermal*: more energetic than typical energy;  
at least 2 superconducting AL gap

# COSMOGENIC BACKGROUND

- $750\mu\text{s}$  is a typical real particle pulse time
- Total time of our samples  $\sim 100,000\ \mu\text{s}$
- Cosmogenic background (muons mostly) interact with the detector (passing the scintillating veto)
  - 1 every  $64.4 \pm 0.1\ \text{s}$
  - energy threshold choice is  $1\ \text{V}$  ( $\approx 6.9\ \text{MeV}$ )

<http://cdms.berkeley.edu/Dissertations/fritts.pdf>

## II. CDMS and the Hunt for Dark Matter

# $V_{\text{BIAS}}$ AND FRONT END BOARD

- The  $V_{\text{bias}}$  is actually on the Front End Board, which ALSO does a part of the read-out electronics

- $V_{\text{bias}}$  sets the TES  $R$  vs.  $T$  Curve      Temperature is fixed at 80mK

## IV. Potential Sources of Noise: Method

# HOW TO UNTANGLE THE SOURCES OF NOISE

### Experiment Modes

- A. Standard Configuration
- B. Normal Conducting
- C. Super Conducting

- 1.  $V_{bias}$  Electronics:** If peaks are due to noise from the  $V_{bias}$  control then they should be bigger or smaller depending on the the overall resistance in the circuit. The amount is known, so the ratio of the peaks should follow this ratio  
 $A/B \sim 1/3$      $A/C \sim 7$
- 2. True Phonon Production:** If noise is due to detector vibrations, then we should not see any noise when we are not sensible to phonons (modes B & C)
- 3. Detector Level Inductive Coupling:** From PSDs it is the same as  $V_{bias}$  **1**, but we can look at correlation between channels/detectors depending on the connections/card dependencies of the channels within each detector
- 4. Other Electronics:** If the noise is due to the electronics after the SQUID (Other Electronics), then the peaks should be in the same place and have the same size regardless of the experiment mode

## IV. Potential Sources of Noise: Method

# BASE NOISE OF THE TES CIRCUIT

- ‘Johnson Noise’
  - Intrinsic of the TES/SQUID circuit
  - Characteristic of the amplification of the TES SQUID pulse
- Depends on the Resistance and Temperature of the elements in the circuit

Amplitude  
of J-Noise in PSD:

$$S_I^2 = \frac{4 k_B (\sum R_i T_i)}{(\sum R_i)^2}$$

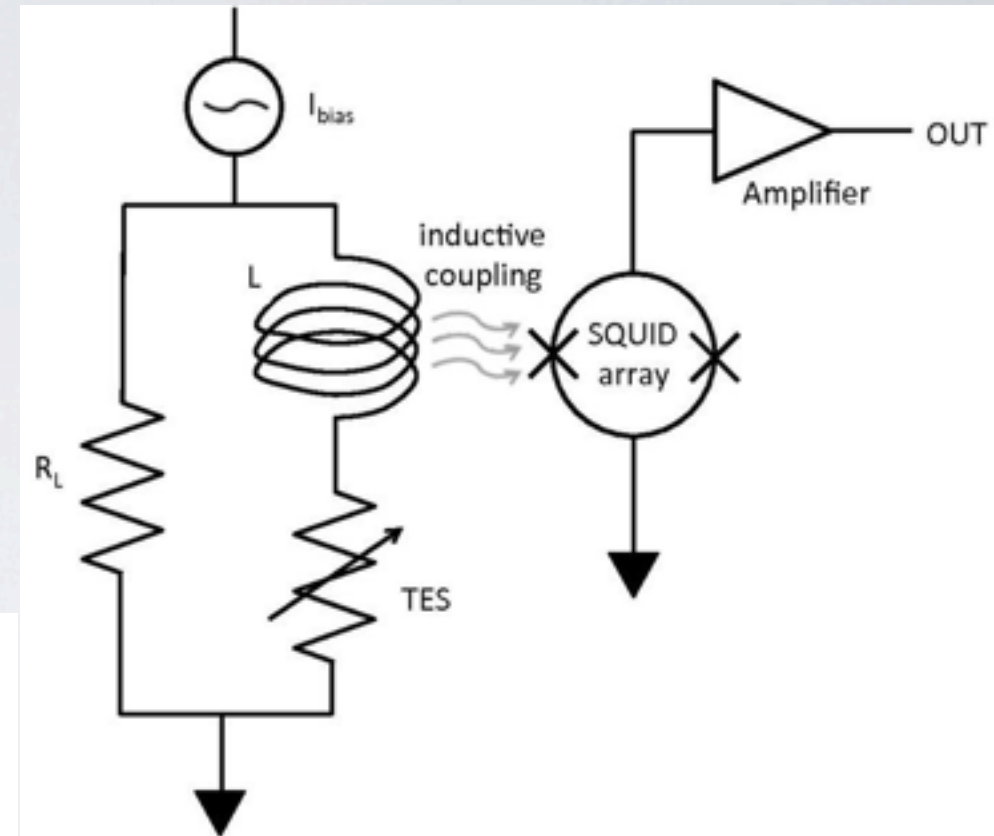

- The cut-off frequency is determined by the impedance

$$\frac{dI}{dV} = \frac{1}{Z} = \frac{1}{(R_L + R_{TES} + \omega L j)}$$

Cut-off frequency

- By setting a  $V_{bias}/I_{bias}$  (from FEB), we set the TES resistance in the circuit

R and T values of the Circuit

Element	Resistance	Temperature
$R_L$	34 m $\Omega$	1.2 K
$R_{TES}$	(0 or 600) m $\Omega$	80 mK

# JOHNSON NOISE AND PARASITIC RESISTANCE

$$S_I^2 = \frac{4 k_{\beta} (\sum R_i T_i)}{(\sum R_i)^2}$$

$$S_{II} = \frac{\sim 1 \text{ pA}}{\sqrt{\text{Hz}}}$$

NC:  $G_T \approx 3.63 \text{ pA} / \sqrt{\text{Hz}} .$   
SC:  $G_T \approx 44 \text{ pA} / \sqrt{\text{Hz}} .$

- Johnson Current
- Parasitic Resistance (Average)

Element	Resistance	Temperature
$R_L$	34 mΩ	1.2 K
$R_{TES}$	(0 or 600) m Ω	80 mK

Element	Resistance	Temperature
$R_{shunt}$	20 mΩ	1.1 K
$R_{Al}$ wire bonds	$2 \times 4 \text{ m}\Omega$	1.1 K
$R_{pins(a)}$	$2 \times 1 \text{ m}\Omega$	4 K
$R_{pins(b)}$	$2 \times 1 \text{ m}\Omega$	1.1 K
$R_{pins(c)}$	$2 \times 1 \text{ m}\Omega$	80 mK
<b><math>R_L</math></b>	<b>34 m Ω</b>	<b>1.2 mK</b>

Std/NC=230mΩ/630mΩ ~ 1/3      Std/SC=230mΩ/30mΩ ~ 7

## IV. Potential Sources of Noise

# B. NORMAL CONDUCTING DATA

- This plot shows what the readout looks like when we are insensitive to phonons
- No big slope at low frequency
- Spikes still exist
- Lower baseline, but that's expected because there is more resistance
- No cut-off here because its off scale.

Amplitude Baseline  
From J-Noise:

3.63 pA /  $\sqrt{\text{Hz}}$

Cut-off frequency from Impedance: 250 kHz  
(Out of range)

## IV. Potential Sources of Noise

### C. SUPERCONDUCTING DATA

- This plot shows what the readout looks like when we are insensitive to phonons, but the amplification on the TES/SQUID circuit is maximum
- Smaller TES resistance gives greater baseline noise
- Spikes are swamped but if spikes persist they are other electronics or (if scaled accordingly)  $V_{\text{bias}}$ /Inductive noise
- 55-60 Hz electronics noise (Mains Hum)
- Lower threshold Cut-off as expected

Amplitude Baseline  
From J-Noise:

44 pA /  $\sqrt{\text{Hz}}$

## IV. Potential Sources of Noise

# DETECTOR READOUT IN NORMAL CONDUCTING DATA

- When the TES has a Temperature/ $V_{\text{bias}}$  configuration that makes it normal conducting, the readout signal is insensitive to phonons in the detector
- No big slope at low frequencies. Noise in the previous plot must be due to phonons 'intrinsic' to the detector somehow
- Spikes still exist, must not be due to phonons, but to some part of the electronics. Note the big spike at 60Hz (suggestive number)
- Lower baseline, but that's expected because there is more resistance
- No 'cut-off' here because its off scale.

Amplitude Baseline  
From Johnson Noise: **3.63 pA /  $\sqrt{\text{Hz}}$**

Cut-off frequency from Impedance: **250 kHz**  
(Out of range)

## IV. Potential Sources of Noise

# DETECTOR READOUT IN SUPERCONDUCTING DATA

- When the  $V_{\text{bias}}$  sets the TES in superconducting mode, again the readout signal is insensitive to phonons in the detector.
- Smaller TES resistance gives greater baseline noise
- Only see one spike at 60Hz again. Other spikes are gone, perhaps swamped with baseline noise?
- Lower threshold Cut-off as expected

## IV. Potential Sources of Noise: Results

# THIRD EXAMPLE: $V_{\text{BIAS}}$ /INDUCTIVE PEAKS

- 60Hz peak is not the same, it is possible that  $V_{\text{bias}}$ /Inductive noise is coupled as well as Other Electronics noise
- Clear peak due to  $V_{\text{bias}}$ /Inductive noise, scales accordingly:
  - Std/SC  $\sim 7$
  - Std/NC  $\sim 1/3$
  - NC/SC  $\sim 21$
- In Standard Bias these peaks could be masked by baseline + phonon noise
- In Superconducting mode peaks must be dominant due to the resistance ratios

## IV. Potential Sources of Noise: Results

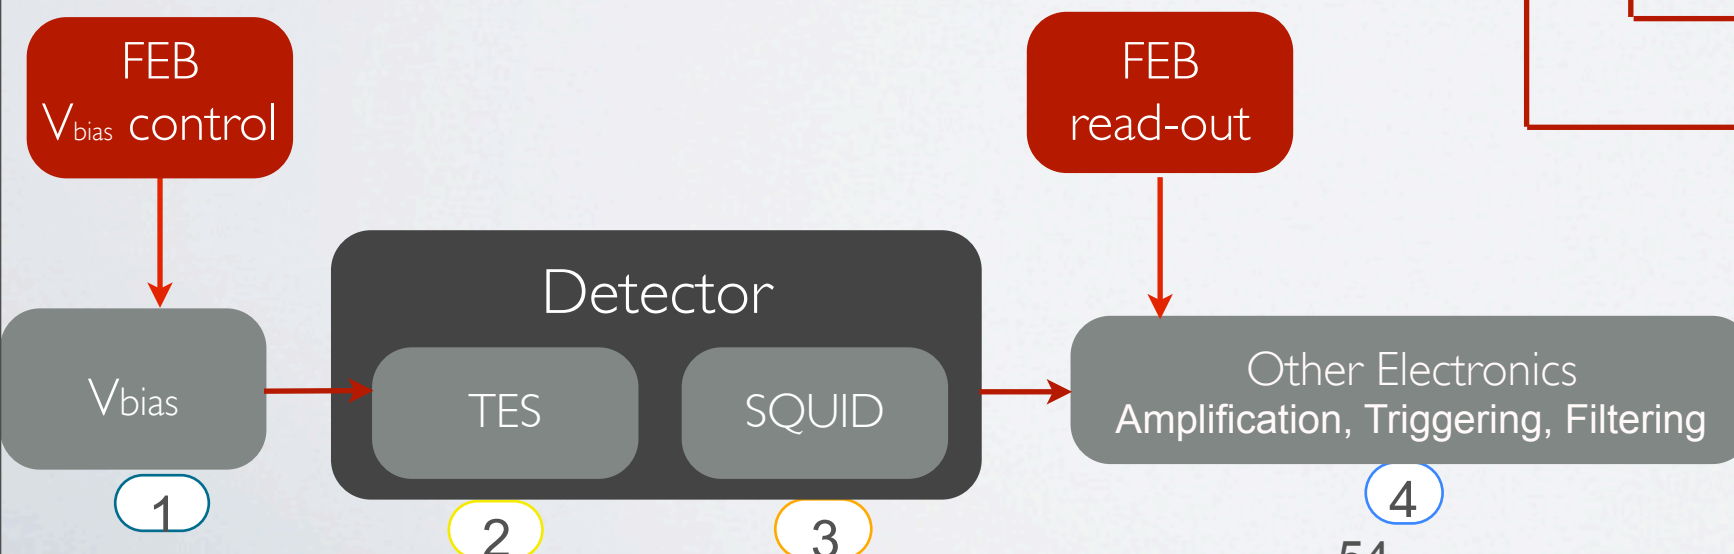

### 4TH EXAMPLE: BORDERLINE $V_{\text{BIAS}}$ / INDUCTIVE PEAKS

- $V_{\text{bias}}$ /Inductive noise can combine with Other Electronics noise
- Don't see a perfect ratio, the downstream electronics noise adds, but it is clearly not a phonon noise (because it is not dominant in Std)

# LIMITATIONS OF THE STUDY

- Unfortunately we are not able to discriminate between a capacitively coupled (TES  $V_{\text{bias}}$ ) noise and an inductively coupled (SQUID) noise, but we can see if the noise is common to phonon channels connected to the same electronics board - Front End Board (FEB) - as opposed to a detector
- The FEB connections to the TES channels are combined:
  - 2 cards per detector
  - 2 channels per side in each card

## IV. Potential Sources of Noise: Results

### RESULTS FOR ALL DETECTORS

- < 60 Hz Background Results:
  - Most of the detectors clearly show real phonon noise

Phonon Dominated (affecting all channels):

Not as Intense, or Not Clear:

iZip

iT1Z1	iT2Z1	iT3Z1	iT4Z1	iT5Z1
iT1Z2	iT2Z2	iT3Z2	iT4Z2	iT5Z2
iT1Z3	iT2Z3	iT3Z3	iT4Z3	iT5Z3

## IV. Potential Sources of Noise: Results

# RESULTS FOR ALL DETECTORS Continued...

- 100 Hz - 1 kHz peaks
  - Different detectors show different noise sources, but overall noise is similar in all channels of the same detector (as opposed to some channels)
  - Other Electronics noise doesn't appear in all channels of same detector
  - All detectors show real phonon source peaks
  - Some show additional  $V_{\text{bias}}$ /Inductive peaks, others show no sources of this kind

Phonon Dominated: 

Inductively /  $V_{\text{bias}}$  Dominated: 

Compromise between both: 

Include odd downstream electronics coupling (at least one peak): 

iZip

iT1Z1	iT2Z1	iT3Z1	iT4Z1	iT5Z1
iT1Z2	iT2Z2	iT3Z2	iT4Z2	iT5Z2
iT1Z3	iT2Z3	iT3Z3	iT4Z3	iT5Z3

# SUMMARY

- Mostly coupled by athermal phonons, or, for non-vibrating detectors through a vbias +downstream coupling mechanism.  
(Of course excluding the ~60Hz Mains Hum, which affects pretty much all detectors).
- The baseline noise (background) in the range  $< 600\text{Hz}$  (and possibly  $< 500\text{Hz}$ ) is phonon coupled, and affects noticeably 13 detectors in all working channels.
- The peaks in the range 100 - 1kHz are both phonon and electronically (vbias +downstream) coupled, a list of dominant mechanism per detector is provided, and few (4/15) detectors include signs of downstream electronics noise (only in some channels 17/28 channels in total).
- Now that we know that the predominant noise is athermal phonon coupled or Vbias +downstream coupled, we can try to make a covariance/correlation study of each phonon channel within the same detector. This can not only tell us effectively if the noise is detector correlated, but it can tell us which frequencies are preferably correlated between channels, and ultimately it may provide ways of suppressing some modes.

[http://titus.stanford.edu/cdms\\_restricted/Soudan/R133/ebook/140707\\_jm/](http://titus.stanford.edu/cdms_restricted/Soudan/R133/ebook/140707_jm/)

# REMARKS

- 100 - 1000 Hz peaks:
  - Most cases it is electronically coupled and phonon coupled
  - Some seem like fft harmonics of the 60Hz peak that keep the SC/Std and NC/Std factors, so it is electronically ( $V_{bias}$ ) coupled
  - In other cases the noise turns on when the detector is in the transitioning phase, which means there is also a phonon coupling
  - Also, in fewer cases some downstream electronics peaks appear (keeping the 1-to-1 ratio)
- A lot of the noise disappears in the Super Conducting mode, the persisting peaks should be electronically coupled, although only the stronger ones persist, and whenever SC/NC show a factor close to 21 the noise is electronics ( $V_{bias}$ /Inductively) related
- For phonon dominated detectors, since the noise peaks seem to be detector related, not FEB/squet/dib related, this helps to discard the downstream electronics and  $V_{bias}$  coupled electronics, although some exceptions occur in the 60Hz peak

# REMARKS

- $<60\text{Hz}$ : phonon coupled: most detectors show relatively flat SC and NC PSDs in this range, while the Std shows an intense background (detailed count in the following section)
- Homogenously decreasing background from 10 - 1kHz: again, seems to be a tail from the  $<60\text{Hz}$  region
- 60Hz peak:
  - Electronically coupled possibly the common 'Mains Hum' affecting all electronics, both downstream electronics and detector electronics
  - In some cases it is also downstream because the peaks are 1-to-1
  - But in other cases it seems like the noise couples inductively (i.e. SC/Std is close to a factor of 7, and NC/Std close to  $1/3$ )
- 100 - 1000 Hz peaks: complicated but most important region
- 2kHz: inductively/vbias coupled (doesn't appear in all detectors/channels)
